## Task 1 : Real-Time Scheduling

## 1.1: Fixed-Priority Scheduling

(maximal 17 points)
A periodic task-set as shown in Table 1 is to be scheduled on a processor. The first release of each task occurs at time zero.

| Task | Computation Time | Period | Deadline |
| :---: | :---: | :---: | :---: |
| $\tau_{1}$ | 2 | 5 | 4 |
| $\tau_{2}$ | 1 | 4 | 3 |
| $\tau_{3}$ | 2 | 8 | 8 |

Table 1: A periodic task-set
(a) (3 points) Construct the scheduling diagram under Deadline Monotonic (DM) preemptive scheduling.

## Sample solution:

Figure 1: Preemptive DM schedule
The priorities are $\tau_{2}>\tau_{1}>\tau_{3}$.
(b) (2 points) Construct the scheduling diagram under DM non-preemptive scheduling (i.e. once started, any task has to run to completion before yielding the processor to the other tasks).

## Sample solution:

Figure 2: Non-preemptive DM schedule
The priorities are the same as before.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik

- 5 und Kommunikationsnetze Computer Engineering and Networks Laboratory
(c) (9 points) Assume preemptive scheduling and DM priority assignment.
(1) (3 points) Does the task-set pass the sufficient schedulability test?

Sample solution: No, it does not, as the following does not hold:

$$
\begin{align*}
2 / 4+1 / 3+2 / 8 & \leq 3\left(2^{1 / 3}-1\right) \\
1.083 & \leq 0.780 \tag{1}
\end{align*}
$$

(2) (6 points) Does the task-set pass the necessary and sufficient schedulability test?

Sample solution: Yes it does, as every task meets its deadline:
$\tau_{2}: \quad R_{2}=1$.
$\tau_{1}: R_{1}=2+\left\lceil\frac{R_{1}}{4}\right\rceil \times 1, R_{1}=3$.
$\tau_{3}: R_{3}=2+\left\lceil\frac{R_{3}}{5}\right\rceil \times 2+\left\lceil\frac{R_{3}}{4}\right\rceil \times 1, R_{3}=8$.
(d) (3 points) Assume non-preemptive fixed-priority scheduling. In the worst-case, how many lower priority jobs can delay the execution of one job? Justify your answer.

## Sample solution:

At most one lower priority job.
We can prove this by contradiction. Suppose there are more than one lower priority jobs that could interfere with the execution of one job; then, when the jobs switch, the system would choose instead of the rest of the lower priority jobs, the job under analysis. Contradiction.

## 1.2: EDF Scheduling

A periodic task-set as shown in Table 2 is to be scheduled on a preemptive processor under Earliest Deadline First (EDF). For a periodic task $\tau_{i}$, we denote its computation time with $C_{i}$, period with $T_{i}$, and relative deadline with $D_{i}$. We assume that the first release of each task occurs at time zero.

| Task | Computation Time | Period | Deadline |
| :---: | :---: | :---: | :---: |
| $\tau_{1}$ | 1 | 4 | 3 |
| $\tau_{2}$ | 1 | 2 | 2 |
| $\tau_{3}$ | 2 | 8 | 8 |

Table 2: A periodic task-set
(a) (2 points) Construct the preemptive EDF scheduling diagram.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik

Sample solution: Notice that over interval [6,8], the order can be swapped as two jobs have the same deadline.

Figure 3: EDF schedule
(b) (2 points) A periodic task-set with constrained deadlines (i.e. $D_{i} \leq T_{i}, \forall \tau_{i}$ ) is schedulable if $\sum_{i} \frac{C_{i}}{D_{i}} \leq 1$. Does the task-set pass this sufficient schedulability test?

Sample solution: It does not, as $1 / 3+1 / 2+2 / 8>1$.
(c) (12 points) The demand bound ( db ) of a periodic task $\tau_{i}$ for any time interval of length $\Delta$ is defined as

$$
\mathrm{db}\left(\tau_{i}, \Delta\right)=\max \left\{\left\lfloor\frac{\Delta-D_{i}}{T_{i}}\right\rfloor+1,0\right\} \cdot C_{i}
$$

It is known that a set of such periodic tasks $\left\{\tau_{i} \mid 1 \leq i \leq n\right\}$ (with arbitrary first release times) is schedulable on a preemptive processor under EDF if and only if

$$
\forall \Delta \geq 0, \sum_{i=1}^{n} \mathrm{db}\left(\tau_{i}, \Delta\right) \leq \Delta
$$

(1) (9 points) Plot the total system db as a function of $\Delta$ for the task-set in Table 2. Based on the above demand bound test, is the system schedulable under EDF?

Sample solution: In $[0,8]$, the demand bound test condition is satisfied. After that, the system just repeats (with a hyper-period of 8 ). Hence, the system is schedulable.

Note, in the Figure we have three lines to represent individual db's of tasks, the thin red lines represents the sum of these or total db , and the thick red line is the supply.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik und Kommunikationsnetze Computer Engineering and Networks Laboratory
Spring 2016 Embedded Systems- Sample solution Page 4

## Sample solution:

Figure 4: System db
(2) (3 points) Explain in a few sentences why passing the demand bound test is a necessary schedulability condition.
Hint: You can think about what db represents.
Sample solution: For an interval length of $\Delta$, the demand bound function of a task represents the maximum workload that must be finished in any interval of length $\Delta$. Therefore, if the demand bound test is not passed, no scheduling algorithm can meet all task deadlines.

## 1.3: Server Scheduling

A periodic task-set as shown in Table 3 is to be scheduled on a preemptive processor. In addition, a job $J$ with unknown arrival time and computation time of 5 units needs to be scheduled on the processor.
(a) (3 points) Assume Rate Monotonic (RM) scheduling for the periodic tasks, while job $J$ is served by a polling server with period $T_{S}=3$ and computation time $C_{S}=0.5$. What is the smallest relative deadline that $J$ can always satisfy?

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich
und Kommunikationsnetze Computer Engineering and Networks Laboratory

| Task | Computation Time | Period | Deadline |
| :---: | :---: | :---: | :---: |
| $\tau_{1}$ | 1 | 4 | 4 |
| $\tau_{2}$ | 2 | 5 | 5 |

Table 3: A periodic task-set

Sample solution: $R_{J}=\left(1+\left\lceil\frac{5}{0.5}\right\rceil\right) \times 3=33$.
(b) (6 points) Assume EDF scheduling for the periodic tasks, while job $J$ is served by a total bandwidth server. What is the smallest relative deadline that $J$ can always satisfy such that the periodic tasks are also schedulable?

Sample solution: $R_{J}=0+\frac{5}{U_{\text {server }}} \geq \frac{5}{1-1 / 4-2 / 5}=14.3$.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik und Kommunikationsnetze Computer Engineering and Networks Laboratory

## Task 2 : Communication \& Low Power Design

(maximal 37 points)

## 2.1: TDMA \& Energy Harvesting

(maximal 11 points)
Four sensor nodes $\left(S_{1}, S_{2}, S_{3}, S_{4}\right)$ transmit messages to a host $H$ over a wireless network with the topology depicted in Figure 5.

Figure 5: Network Topology
Communication occurs during frames that repeat periodically. Each frame is composed of four slots of equal duration $T_{\text {slot }}$, with one slot for each sensor. Sensors transmit messages during slots according to a Time Division Multiple Access (TDMA) protocol. The radio of the host and each sensor supports a data rate within the range of $[1,10]$ Mbps ( $10^{6}$ bits per second), and the propagation delay is negligible.
(a) (5 points) Assume each sensor $S_{i}$ is assigned a slot duration $T_{\text {slot }}=50 \mathrm{~ms}$. Each sensor makes periodically available $125 \mathrm{~kb}\left(1 \mathrm{~kb}=10^{3}\right.$ bits) with a period of 250 ms . What is the minimum data rate given that the maximum allowed latency is 200 ms ?
Definition: Latency is the time between making data available for transmission at the sensor and receiving the data at the host.

## Sample solution:

Since $T_{\text {slot }}$ is already set, a maximum latency of 200 ms implies that each node transmits their 125 kb during one frame. The minimum data rate is then $D=125 \mathrm{~kb} / 50 \mathrm{~ms}=$ 2.5Mbps.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik und Kommunikationsnetze Computer Engineering and Networks Laboratory
(b) (6 points) Consider the TDMA schedule shown in Figure 6, which includes additional time $T_{\text {processing }}$ for the host to process the received messages. During $T_{\text {processing }}$, the host must compute for $10^{5}$ cycles. The host processor can execute at a clock frequency $F$ from the discrete set $\{5,10,20\} \mathrm{MHz}$. Assume that frequency is proportional to voltage ( $F \sim V_{\mathrm{dd}}$ ) and the power $P$ satisfies $P \sim V_{\mathrm{dd}}^{2} * F$.

Frame 1

Figure 6: TDMA schedule including host processing time.

If $T_{\text {slot }}=10 \mathrm{~ms}$ and $T_{\text {frame }} \leq 50 \mathrm{~ms}$, find the host frequency which minimizes the energy required for processing. Justify your answer.

## Sample solution:

Given the above inequality, it follows that $T_{\text {processing }} \leq 10 \mathrm{~ms}$. For frequencies $F=$ $\{5 M, 10 M, 20 M\}$, their processing time is $T_{\text {processing }}=\{20 \mathrm{~ms}, 10 \mathrm{~ms}, 5 \mathrm{~ms}\}$, respectively. Hence, $F=5 M$ is not a valid frequency.
The energy consumed when $\mathrm{F}=10 \mathrm{M}$ is $E_{10 \mathrm{M}} \sim 10 \mathrm{MHz} * V_{d d, 10 M}^{2} * 10 \mathrm{~ms}=10^{5} * V_{d d, 10 M}^{2}$.
The energy consumed when $\mathrm{F}=20 \mathrm{M}$ is $E_{20 M} \sim 20 \mathrm{MHz} * V_{d d, 20 M}^{2} * 5 \mathrm{~ms}=10^{5} * V_{d d, 20 M}^{2}$.
Given that $F \sim V_{d d}$, it follows that $V_{d d, 10 M}<V_{d d, 20 M}$. Consequently, $\mathrm{F}=10 \mathrm{M}$ consumes the least energy.

Eidgenössische Technische Hochschule Zürich
Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik und Kommunikationsnetze Computer Engineering and Networks Laboratory

## 2.2: Dynamic Voltage Scaling

Consider a processor whose dynamic power dissipation when running with a clock frequency $f$ in Hz , is given by $P_{\text {dynamic }}=\left(\frac{f}{10^{6} \mathrm{~Hz}}\right)^{3} \mathrm{~mW}$. It is assumed that the processor has negligible static and leakage power dissipation.
The processor must execute the following task-set:

| Task | $\tau_{1}$ | $\tau_{2}$ | $\tau_{3}$ |
| :---: | :---: | :---: | :---: |
| Arrival Time (ms) | 0 | 2 | 4 |
| Absolute Deadline (ms) | 6 | 5 | 9 |
| Cycles $\left(\times 10^{3}\right)$ | 3 | 9 | 3 |

Table 4: Task set.
Assume the clock frequency of the processor can be selected from a continuous range of frequencies. Apply the online YDS algorithm and plot the schedule in Figure 7. How much energy does the processor consume to complete all tasks?

## Sample solution:

Apply the online YDS algorithm using intensity function $G\left[z_{1}, z_{2}\right]=\frac{\sum_{i \in V^{-}} c_{i}}{z_{2}-z_{1}}$.
Step 1:
$\tau_{1}: G[0,6]=3 / 6$
Schedule task $\tau_{1} @ 0.5 \mathrm{MHz}$

Step 2:
$\tau_{2}: G[2,5]=9 / 3$
$\tau_{1}: G[2,6]=11 / 4$
Schedule task $\tau_{2} @ 3 \mathrm{MHz}$

Step 3:
$\tau_{2}: G[4,5]=3 / 1$
$\tau_{1}: G[4,6]=5 / 2$
$\tau_{3}: G[4,9]=8 / 5$
Schedule task $\tau_{2} @ 3 \mathrm{MHz}$

Step 4:
$\tau_{1}: G[5,6]=2 / 1$

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik
TK und Kommunikationsnetze Computer Engineering and Networks Laboratory

Schedule task $\tau_{1} @ 2 \mathrm{MHz}$

Step 5:
$\tau_{3}: G[6,9]=3 / 3$
Schedule task $\tau_{3} @ 1 \mathrm{MHz}$

Figure 7: Online YDS Schedule.

To calculate the energy, different methods can be used. One is to convert the above figure to power, given the $P_{\text {dynamic }}$ equation, and calculate the area underneath the curve. Since $P_{\text {avg }}=0.125 *(2 / 9)+27 *(3 / 9)+8 *(1 / 9)+1 *(3 / 9)=10.25 m W$, it follows that $E_{\text {consumed }}=P_{\text {avg }} * T=10.25 \mathrm{~mW} * 9 \mathrm{~ms}=92.25 u \mathrm{~J}$.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik und Kommunikationsnetze Computer Engineering and Networks Laboratory

## 2.3: Dynamic Power Management

Consider a processor supporting two modes: IDLE and ACTIVE. The power dissipation is $P_{\text {idle }}=5 \mathrm{~mW}$ and $P_{\text {active }}=50 \mathrm{~mW}$, respectively. The processor must schedule the following periodic task-set:

| Task | $\tau_{1}$ | $\tau_{2}$ | $\tau_{3}$ |
| :---: | :---: | :---: | :---: |
| Period (ms) | 10 | 10 | 10 |
| Arrival of First Task (ms) | 0 | 3 | 5 |
| Relative Deadline (ms) | 3 | 7 | 10 |
| Execution Time (ms) | 1 | 1 | 2 |

Table 5: Periodic task-set.
Definition: A workload-conserving scheduler always executes a task when the ready queue is not empty.
Definition: The average power dissipation between time 0 and $T$ is given by $P_{\text {avg }}=\frac{1}{T} \int_{0}^{T} P(\tau) d \tau$.
(a) (6 points) Assuming zero energy and time overhead between IDLE and ACTIVE mode, plot the power dissipation during two periods for a workload-conserving schedule using Figure 8. The processor is in IDLE mode at time 0 . What is the average power $P_{\text {avg }}$ between time 0 ms and 20 ms ?

## Sample solution:

We can calculate the average power of one period by taking into account the time in each system mode. Since the schedule in both periods are the same, the average of two periods is the same as the average of one: $P_{\text {avg }}=P_{\text {active }} * 4 / 10+P_{\text {idle }} * 6 / 10=23 \mathrm{~mW}$.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik
TIL und Kommunikationsnetze Computer Engineering and Networks Laboratory

Figure 8: Solution for workload-conserving scheduler.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik und Kommunikationsnetze Computer Engineering and Networks Laboratory
(b) (6 points) Now assume that there is a third mode called SLEEP, with $P_{\text {sleep }}=0 \mathrm{~mW}$. The system modes and allowed transitions, along with their energy and time overheads, are shown in Figure 9. Power dissipation during a mode transition is constant. A transition to ACTIVE mode occurs when there is at least one task in the ready queue. Plot the power dissipation during two periods for an energy-minimizing, workloadconserving schedule using Figure 10. The processor is in SLEEP mode at time 0 . What is the average power $P_{\text {avg }}$ between time 0 ms and 20 ms ?

Figure 9: System modes and allowed transitions.

## Sample solution:

First, we have to calculate the break-even time $t_{\text {bev }} \geq 7.5 \mu \mathrm{~J} / 5 \mathrm{~mW}=1.5 \mathrm{~ms}$. Since the gaps between tasks $\tau_{1}$ and $\tau_{2}$ are only 1 ms long, the system should stay in IDLE during these gaps. After task $\tau_{3}$, the 3ms gap is greater the break-even time, meaning the system should enter SLEEP mode. Lastly, the average power during the switch from SLEEP to ACTIVE, $P_{\text {switch }}=E_{\text {switch }} / t_{\text {switch }}=7.5 \mathrm{~mW}$. Now, we can calculate the average power of one period by taking into account the time in each system mode. Since the schedule in both periods are the same, the average of two periods is the same as the average of one: $P_{\text {avg }}=P_{\text {active }} * 4 / 10+P_{\text {switch }} * 1 / 10+P_{\text {idle }} * 2 / 10+P_{\text {sleep }} * 3 / 10=$ 21.75 mW .

## Task 3 : Architecture Synthesis

(maximal 41 points)

## 3.1: Architecture Synthesis Fundamentals

Mark the following statements as true or false and provide a one sentence explanation.

- (1 point) In a sequence graph, a LOOP node is considered an operation or task node.

## Sample solution:

## True

$\boxtimes$ False

Explanation: Sequence graphs have operation or tasks nodes, and hierarchy nodes. A LOOP node is the latter.

- (1 point) ALAP (as late as possible) scheduling provides a schedule with maximal latency, when limited resources are available.

## Sample solution:

## $\square$ True

$\boxtimes$ False
Explanation: ALAP scheduling produces minimal latency, assuming unlimited resources.

- (1 point) A dependence graph does not specify a schedule.

## Sample solution:

$$
\boxtimes \text { True }
$$False

Explanation: A dependence graph specifies partial order between operations, not the schedule.

- (1 point) In a marked graph, tokens on edges can be interpreted as data stored in a LIFO (last in, first out) queue.

## Sample solution:

## True

$\boxtimes$ False
Explanation: Tokens correspond to data stored in FIFO queues.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich
und Kommunikationsnetze Computer Engineering and Networks Laboratory

- (1 point) A marked graph can be implemented in hardware.

## Sample solution:

## ® True

FalseExplanation: There are different possibilities of marked graphs implementation, both in hardware and software.

- (1 point) In List scheduling, node priorities change as the algorithm executes through different time steps.

## Sample solution:

## True

$\boxtimes$ False
Explanation: In list scheduling, priorities are determined a priori and do not change during execution.

- (1 point) For a given problem, a heuristic algorithm guarantees optimal solutions.

## Sample solution:

## True

$\boxtimes$ False
Explanation: Heuristics are non-optimal algorithms.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik und Kommunikationsnetze Computer Engineering and Networks Laboratory

## 3.2: List Scheduling

Consider the sequence graph in Figure 11, and answer the following questions.

Figure 11: A sequence graph
(a) (10 Points) Suppose that one multiplier and two adders are available as resources. Addition and multiplication take one and two time units on the adders ( $r_{1}, r_{2}$ ) and multiplier $\left(r_{3}\right)$, respectively. The first operation starts at $t=0$ and the top node ('nop') is executed in zero time. The priority is assigned for each operation as the maximal distance to the bottom node ('nop'). The maximal distance is defined as the number of edges on the longest path between two nodes. Fill out Table 6 using the List scheduling algorithm. For a timestep $t: U_{t, k}$ denotes the set of operations that are ready to be scheduled on resource $r_{k}$. $S_{t, k}$ denotes the set of operations that start at time $t$ on resource $r_{k}$. $T_{t, k}$ denotes the set of operations in execution at time $t$ on resource $r_{k}$.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik und Kommunikationsnetze Computer Engineering and Networks Laboratory

| $t$ | $k$ | $U_{t, k}$ | $T_{t, k}$ | $S_{t, k}$ |
| :---: | :---: | :--- | :--- | :--- |
| 0 | $r_{1}, r_{2}$ | $\nu_{1}, \nu_{4}, \nu_{5}$ | - | $\nu_{1}, \nu_{5}$ |
|  | $r_{3}$ | $\nu_{2}, \nu_{3}$ | - | $\nu_{2}$ |
| 1 | $r_{1}, r_{2}$ | $\nu_{4}, \nu_{9}$ | - | $\nu_{4}, \nu_{9}$ |
|  | $r_{3}$ | $\nu_{3}$ | $\nu_{2}$ | - |
| 2 | $r_{1}, r_{2}$ | $\nu_{11}$ | - | $\nu_{11}$ |
|  | $r_{3}$ | $\nu_{3}, \nu_{6}$ | - | $\nu_{6}$ |
| 3 | $r_{1}, r_{2}$ | - | - | - |
|  | $r_{3}$ | $\nu_{3}$ | $\nu_{6}$ | - |
| 4 | $r_{1}, r_{2}$ | $\nu_{8}$ | - | $\nu_{8}$ |
|  | $r_{3}$ | $\nu_{3}$ | - | $\nu_{3}$ |
| 5 | $r_{1}, r_{2}$ | - | - | - |
|  | $r_{3}$ | $\nu_{10}$ | $\nu_{3}$ | - |
| 6 | $r_{1}, r_{2}$ | $\nu_{7}$ | - | $\nu_{7}$ |
|  | $r_{3}$ | $\nu_{10}$ | - | $\nu_{10}$ |
| 7 | $r_{1}, r_{2}$ | - | - | - |
|  | $r_{3}$ | - | $\nu_{10}$ | - |
| 8 | $r_{1}, r_{2}$ | $\nu_{12}$ | - | $\nu_{12}$ |
|  | $r_{3}$ | - | - | - |

Table 6: Table for Task 3.2. (a)

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich
und Kommunikationsnetze Computer Engineering and Networks Laboratory
(b) (1 Point) What is the corresponding latency?

Sample solution:
$L=9$.
(c) (2 Points) If it is allowed to add a single additional hardware unit, an adder or a multiplier, which resource should be added to reduce the latency? Explain why.

## Sample solution:

The critical path $(2 \rightarrow 6 \rightarrow 8 \rightarrow 10 \rightarrow 12)$ bounds the minimum latency. At time $t=5$ the lack of multipliers introduces a delay. An additional multiplier would avoid this delay, while an additional adder would not reduce the latency.

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik und Kommunikationsnetze Computer Engineering and Networks Laboratory

## 3.3: Timing Constraints

Consider the sequence graph and execution times $w\left(f_{i}\right)$ of tasks $f_{i}$ in Figure 12, answer the following questions.

| Task | $w\left(f_{i}\right)$ |
| :---: | :---: |
| $f_{1}$ | 1 |
| $f_{2}$ | 5 |
| $f_{3}$ | 1 |
| $f_{4}$ | 2 |
| $f_{5}$ | 2 |
| $f_{6}$ | 2 |
| $f_{7}$ | 4 |
| $f_{8}$ | 3 |
| $f_{9}$ | 2 |
| $f_{10}$ | 3 |
| $f_{11}$ | 2 |

Figure 12: A sequence graph and execution times
(a) (2 Points) Complete the Weighted Constraints Graph $G_{C}=\left(V_{C}, E_{C}, d\right)$ by annotating edges with numbers in Figure 12.

## Sample solution:

See Figure 13.
(b) (5 Points) Formulate the following constraints using $\tau\left(f_{i}\right)$ as the start time of task $f_{i}$. Add appropriate annotated edges to the constraint graph $G_{C}$ in Figure 12.
i) $f_{2}$ should start no earlier than 5 time units after the start of $f_{3}$.

## Sample solution:

$$
\tau\left(f_{2}\right) \geq \tau\left(f_{3}\right)+5 \Rightarrow \tau\left(f_{2}\right)-\tau\left(f_{3}\right) \geq 5
$$

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich
und Kommunikationsnetze Computer Engineering and Networks Laboratory
ii) $f_{4}$ should finish no earlier than 3 time units after the start of $f_{5}$.

## Sample solution:

$$
\tau\left(f_{4}\right)+2 \geq \tau\left(f_{5}\right)+3 \Rightarrow \tau\left(f_{4}\right)-\tau\left(f_{5}\right) \geq 1
$$

iii) $f_{9}$ should start no later than 8 time units after the finish of $f_{5}$.

## Sample solution:

$$
\tau\left(f_{9}\right) \leq \tau\left(f_{5}\right)+2+8 \Rightarrow \tau\left(f_{5}\right)-\tau\left(f_{9}\right) \geq-10
$$

iv) $f_{10}$ should start exactly 3 time units after the start of $f_{11}$.

## Sample solution:

$\tau\left(f_{10}\right)=\tau\left(f_{11}\right)+3 \Rightarrow \tau\left(f_{11}\right)-\tau\left(f_{10}\right) \geq-3 \wedge \tau\left(f_{10}\right)-\tau\left(f_{11}\right) \geq 3$
v) $f_{10}$ should finish no later than 14 time units after the finish of $f_{3}$.

## Sample solution:

$$
\tau\left(f_{10}\right)+3 \leq \tau\left(f_{3}\right)+1+14 \Rightarrow \tau\left(f_{3}\right)-\tau\left(f_{10}\right) \geq-12
$$

(c) (5 Points) In case of unlimited resources, does a feasible schedule exist for the given sequence graph and all of the above timing constraints? Justify your answer.

## Sample solution:

No. There exist positive cycles in $G_{C}$, i.e $f_{3}, f_{2}, f_{6}, f_{9}, f_{11}, f_{10}, f_{3}$. See Figure 13 .

## 3.4: Iterative Algorithm

Consider the marked graph $G_{M}$ and the task execution times in Figure 14, and answer the following questions.

| Task | $\nu_{1}$ | $\nu_{2}$ | $\nu_{3}$ | $\nu_{4}$ | $\nu_{5}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $w\left(\nu_{i}\right)$ | 1 | 2 | 1 | 1 | 2 |

Figure 14: A marked graph with task execution times
(a) (5 points) Formulate all existing dependencies in Figure 14 from $\nu_{i}$ to $\nu_{j}$ in the form of

$$
\tau\left(\nu_{j}\right)-\tau\left(\nu_{i}\right) \geq w\left(\nu_{i}\right)-d_{i j} \times P,
$$

where $P$ is the minimum iteration interval.
Sample solution:

$$
\begin{aligned}
& \tau\left(\nu_{2}\right)-\tau\left(\nu_{1}\right) \geq 1 \\
& \tau\left(\nu_{3}\right)-\tau\left(\nu_{2}\right) \geq 2 \\
& \tau\left(\nu_{4}\right)-\tau\left(\nu_{3}\right) \geq 1 \\
& \tau\left(\nu_{5}\right)-\tau\left(\nu_{3}\right) \geq 1 \\
& \tau\left(\nu_{2}\right)-\tau\left(\nu_{5}\right) \geq 2-1 \times P
\end{aligned}
$$

Eidgenössische Technische Hochschule Zürich Swiss Federal Institute of Technology Zurich

Institut für Technische Informatik und Kommunikationsnetze Computer Engineering and Networks Laboratory
(b) (4 Points) Function $\nu_{2}$ uses the result of $\nu_{5}$ from the previous iteration. Suppose that any arbitrary number of tokens can be inserted on this edge to reduce $P$ using functional pipelining. Assuming unlimited resources, and that the same operation of different iterations cannot be executed in parallel or overlap, how many tokens should be added on the edge $\nu_{5} \rightarrow \nu_{2}$ to achieve the minimal iteration interval? To justify your answer, draw the pipelined schedule for four iterations in Figure 15. Determine the latency $L$ of this schedule.

## Sample solution:

Two more tokens should be added. $P=2$ and $L=6$. See Figure 15 for the schedule.

Figure 15: Scheduling grid for Task 3.4 (b)
